Profiling Households Based on supermarket consumption patterns

# Project Structure:

Data insights

cholesterol

## Health and Nutrition:

Difference btwn both

### How do the clients food habits look like?

Consumption-explained correlations: nutriments show natural correlations amongst food articles (*center*): however, we dont' find the same correlations in the "average soup" people eat (*left*). By subtracting the latter by the former, we obtain correlations that are not explained by the food itself.(*right*)

Cholesterol rate: Assuming normal distribution, low income households showed a higher average cholesterol consumption than wealthy ones under a test.

This shows that given its data, a supermarket possesses the required information to detect unhealthy diet behavior early enough in their development, opening the question of its responsability towards the consumer.

Since some households showed unhealthy habits, we developed a tool able to detect excessive consumers outliers for any nutrient.

Unhealthy diet detection: the 4 plots highlight household average consumption respectively for carbohydrate(tl) cholesterol (tr) energy (bl) and fatty-acids (br). Excessive consumers are shown in red.

## Household clustering:

What underlying groups can we discover among the households by clustering according to consumption habits?

# Age distributions Drivers Passive Passive Drinkers Parents Age category

Insights
Parents: median age is 25-34, no older couples
Drivers: includes age groups

<u>Passive:</u> includes older individuals, is expected since consumerism tends to decrease with age

Aggregated transaction data can be used to group items into categories, and use this categories to cluster users. Clusters and outliers can be used to profile users and get their demographic information.

## Alcohol timeseries:

Discovery of consumption patterns suggestive of alcoholism were found among the households.

Top: Seems to struggle with alcohol consumption. The amount consumed varies a lot and switches between excessive consumption and periods of abstinence.

Daily Alcohol consumption of a single household

Bottom: Time series that represents more frequent consumption of alcohol in very small doses. May be associated with alcoholism.

## Network of items:

## What do transactions tell us about the items themselves?

We looked at co-occurrences in shopping carts and built an undirected graph illustrating relations between items.

Every edge represents items that were bought the most together relative to their overall popularity.

There is a strongly connected component in the middle containing popular food items and some connected components with very interesting patterns.

Edges between items give insight about their relations. These relations are sometimes trivial, but sometimes they reflect particularities of the community and its culture.

# Sample Groups: Pizza Preparation PETRO PIZZA ANCHED NAMED TO STANDARD TO STAN

The degree distribution shows that the most central items are not very healthy items such as snacks and canned foods.

This indicates that contrary to popular items such as milk or bananas, central items are bought together often relative to their individual popularity.

Transaction data can be considered as a form of fingerprint because it reveals a great deal of information about people. We can study nutrition patterns, consumption patterns and items relations. With this toy dataset, we open your eyes to how much big companies probably know about you, and their potential to do good or evil with this knowlege.
